

Name : Ankit Kumar Singh

Roll No. 150101086

Data is collected at different times of day from Team Viewer App (on linux environment). Data can be viewed here <[link](#)>

Networks Lab_Assignment2

Date: 21st Feb'18

Sol1.Protocol hierarchy observed : (All the mentioned packet format can be seen as entries in ques 2. which are explained in much depth there.)

Physical layer: Ethernet frame is prefixed with a preamble(56 bits of alternating (0&1)'s) and SFD(start frame delimiter). But these are removed by Wireshark and hence not observed in the Frame.

Data Link Layer: Ethernet II

Ethernet frame here starts with Ethernet header which includes Dest. MAC address and Source MAC address. This is followed by Type/Length of payload data for any protocol like IP etc. This is

followed by Payload from above layers. Then comes Frame check sequence(FCS) 32-bit cyclic redundancy check used to detect corruption in data.

Preamble(8B)	Dest. Address(6B)	Source Address(6B)	Type/Length(2B)	User Data(46-1500B)	FCS(4 B)
--------------	-------------------	--------------------	-----------------	---------------------	----------

Network Layer :IPv4 It is the backbone of TCP/IP suite. It is responsible for identifying hosts based on their logical address. It uses 32-bit address space to uniquely identify the hosts on network and makes best effort to deliver packets to destined host. Packet contains IP header , ICMP Header , ICMP payload, IP Packet Header consists of IP Version , IHL(IP header length), Total length, TTL(time to leave), Identification number, flags and offset, source and destination IP address. ICMP header contains message type, code and checksum. ICMP payload contains data from above layer

IP Datagram				
	Bits 0–7	Bits 8–15	Bits 16–23	Bits 24–31
IP Header (20 bytes)	Version/IHL	Type of service	Length	
	Identification		flags and offset	
	Time To Live (TTL)	Protocol	Checksum	
	Source IP address			
	Destination IP address			
ICMP Header (8 bytes)	Type of message	Code	Checksum	
	Header Data			
ICMP Payload (optional)	Payload Data			

Transport Layer: TCP It provides the reliable, ordered and error-checked delivery of a stream of octets between application running on hosts communicating by an IP address. Its Segment consists of 2 parts : Segment Header and a data section. Header is shown in the figure. It consists of source port number, destination port number, sequence number, acknowledgement number, data offset, reserved bits, control flags, window size, checksum, urgent pointer and optional data. Data part contains IP packet/data from above layer..

Transmission Control Protocol (TCP) Header

source port number 2 bytes				destination port number 2 bytes			
sequence number 4 bytes							
acknowledgement number 4 bytes							
data offset 4 bits		reserved 3 bits		control flags 9 bits		window size 2 bytes	
checksum 2 bytes				urgent pointer 2 bytes			
optional data 0-40 bytes							

Transport Layer: UDP It is a message oriented protocol that provides no guarantee to upper layer protocol for message delivery and do not retain state of UDP once message is sent. Its packet contains(Header and Data). Its header contains 4 fields each of 2 Bytes, namely, Source port, Destination port, length and UDP checksum.

Source Port	Destination Port
Length	UDP Checksum
Data	

Application Layer: DNS DNS is a decentralized domain name resolving system for various services connected to WAN or LAN. It involves query asked by some client and IP resolved by DNS server. The process is recursive(i.e if one server doesn't know the answer it asks some other dns server as defined). In short

Transaction ID	Flags	12 bytes
Question count	Answer RR count	
Authority RR count	Additional RR count	
Question entries (variable length)		Variable length
Answer RRs (variable length)		
Authority RRs (variable length)		
Additional RRs (variable length)		

it provides a mapping from domain name to IP addresses. Packet format, as shown, contains Transaction ID, Flags, Questions/Answer/Authorised nameserver/Additional info counts, Questions/Answer/Authorised nameserver/Additional info data.

Apart from this protocols very few other packets of other protocol were observed: **DCERPC(3/50k)** and **ESP(1/50k)** from the same IP address. But their purpose is unclear since they were not observed in large quantity and their occurrence was random. Also **NTP** packets were found but not always and source unknown.

Sol2.

(observed in raw_data5.pcapng)

1. Ethernet II : Data Link Layer

```
Ethernet II, Src: ChiconyE_2c:23:87 (4c:bb:58:2c:23:87), Dst: 66:db:43:51:c3:73
  ▶ Destination: 66:db:43:51:c3:73 (66:db:43:51:c3:73)
  ▶ Source: ChiconyE_2c:23:87 (4c:bb:58:2c:23:87)
  Type: IPv4 (0x0800)
```

Destination : Gives the 6 bytes MAC address of the destination NIC/device adapter.

Source : Gives the 6 bytes MAC address of the source NIC/device adapter.

Type : 2 byte field to indicate upper layer protocol to be used.

2. Internet Protocol Version 4(IPv4): Network Layer

```
Internet Protocol Version 4, Src: 192.168.43.10, Dst: 217.146.11.2
  0100 .... = Version: 4
  .... 0101 = Header Length: 20 bytes (5)
  ▶ Differentiated Services Field: 0x00 (DSCP: CS0, ECN: Not-ECT)
    Total Length: 145
    Identification: 0x4d26 (19750)
  ▶ Flags: 0x02 (Don't Fragment)
    Fragment offset: 0
    Time to live: 64
    Protocol: TCP (6)
    Header checksum: 0x1cfa [validation disabled]
    [Header checksum status: Unverified]
    Source: 192.168.43.10
    Destination: 217.146.11.2
    [Source GeoIP: Unknown]
  ▶ [Destination GeoIP: AS42473 ANEXIA Internetdienstleistungs GmbH, India, Mumbai, 16, 18.975000, 72.825798]
```

Version : Version of IP protocol used.

Header Length : Size of the entire IP header.

Differentiated Services Field : Contains 2 fields. DSCP(Differentiated Services Code Point) packet header value that can be used to indicate the level of service requested for traffic, such as high priority or best effort delivery and ECN(Explicit Congestion Notification).

Total length: Size of IP packet(Header+ Payload).

Identification : packet number so that fragmented part can be uniquely identified.

Flags : Indicates that packet is fragmented or not.

Fragment Offset : if fragmented tells the position of fragment in all fragments.

Time to live(TTL) : puts a limit on time(hops it passes) a packet can be valid/exists on network.

Protocol : Upper level protocol used in the payload.

Header Checksum : checks for error and attempts to correct the header

Source : IP address of my PC(device used for connection). Dynamic IP allocated by Hotspot.

Destination : IP address of the address of destination server.

3. UDP (User Datagram Protocol): Transport layer

```
User Datagram Protocol, Src Port: 53, Dst Port: 46895
  Source Port: 53
  Destination Port: 46895
  Length: 437
  Checksum: 0xcb4d [unverified]
  [Checksum Status: Unverified]
  [Stream index: 2]
```

Source Port : Port of the client/source used to connect to the receiver/dest.

Destination Port : Port of the destination/ receiver used for connection.

Length : Size of UDP datagram (Header + Payload)

Checksum : Used for error detection and correction

4. TCP(Transmission Control Protocol) : Transport Layer

```
Transmission Control Protocol, Src Port: 46606, Dst Port: 5938, Seq: 17725, Ack: 17944, Len: 93
  Source Port: 46606
  Destination Port: 5938
  [Stream index: 1]
  [TCP Segment Len: 93]
  Sequence number: 17725      (relative sequence number)
  [Next sequence number: 17818 (relative sequence number)]
  Acknowledgment number: 17944 (relative ack number)
  Header Length: 32 bytes
  ▶ Flags: 0x018 (PSH, ACK)
  Window size value: 584
  [Calculated window size: 74752]
  [Window size scaling factor: 128]
  Checksum: 0x7560 [unverified]
  [Checksum Status: Unverified]
  Urgent pointer: 0
  ▶ Options: (12 bytes), No-Operation (NOP), No-Operation (NOP), Timestamps
  ▶ [SEQ/ACK analysis]
```

Source Port and Destination port as in UDP.

Sequence Number: Data from above layer is divided into IP packets, indicates relative sequence amongst all.

Ack Number : acknowledgment of the packet recieved at other end.(indicates Piggybacking).

Header Length : length of TCP Header.

Flags: Ack: Acknowledges received data and PSH push data immediately.

Window Size value: buffer space available for receiving packets.

Checksum : Error detection and correcting code.

Urgent Point : Point to report when reciever needs some imp. Info.

Options : Other imp info like timestamps etc. Used in tcp communication.

5. DNS(Domain Name System): Application layer

```
Domain Name System (query)
[Response In: 11]
Transaction ID: 0x8268
▶ Flags: 0x0100 Standard query
Questions: 1
Answer RRs: 0
Authority RRs: 0
Additional RRs: 0
▼ Queries
  ▶ ping3.teamviewer.com: type A, class IN
```

Transaction ID: 2 Byte identification field generated by device/application which created DNS query.

Flags: To indicate one of the following :query, response, opcode, recursion query needed, non-authenticated etc.

Questions/Answer/Authority/Additional: Number of queries/answer/authority records/additional records.

Queries/Answer/Authoritative nameservers/Additional records: Details/data related to repective values.

Sol3.

When the team viewer app is opened it sends DNS query for ping3.teamviewer.com(most probably to check whether a connection to team viewer server can be made) for both Ipv4 and Ipv6 results.

192.168.43.10	192.168.43.1	DNS	80 Standard query 0x1e75 A ping3.teamviewer.com
192.168.43.1	192.168.43.10	DNS	144 Standard query response 0x1e75 A ping3.teamviewer.com A :
192.168.43.10	192.168.43.1	DNS	80 Standard query 0x198d AAAA ping3.teamviewer.com
192.168.43.1	192.168.43.10	DNS	192 Standard query response 0x198d AAAA ping3.teamviewer.com

This is followed by TCP 3-way handshake as shown. First client app sends SYN packet to host, host sends SYN-ACK to the client. Client replies with ACK. Once this ACK is received by the host , connection is established. This method is reffered to as TCP SYN-SYN-ACK handshaking method based on the sequence of

method used. This mechanism was designed so that two computers attempting to communicate can negotiate the parameters of the network TCP socket connection before transmitting data.

192.168.43.10	217.146.26.212	TCP	74 39290 → 5938 [SYN] Seq=0 Win=2920
217.146.26.212	192.168.43.10	TCP	74 5938 → 39290 [SYN, ACK] Seq=0 Ack=
192.168.43.10	217.146.26.212	TCP	66 39290 → 5938 [ACK] Seq=1 Ack=1 Win=

After this DNS query (Name: master6.teamviewer.com) is performed followed by TCP handshake (to register the current instance of the Team Viewer app). Again a query (Name: server19403.teamviewer.com, kept changing) is performed. After this TCP handshake is again performed and connection to fixed IP is established. (This is used as mapping if other peer wants to connect to this instance).

Along with the TCP handshake there is another imp message sequence that takes place i.e [PSH ACK] and [ACK]. Here PSH is an indication by the sender that, if the receiving machine's TCP implementation has not yet provided the data it's received to the code that's reading the data (program, or library used by a program), it should do so at that point. There is a coupling between the push function and the use of buffers of data that cross the TCP/user interface. Each time a PUSH flag is associated with data placed into the receiving user's buffer, the buffer is returned to the user for processing even if the buffer is not filled. If data arrives that fills the user's buffer before a PUSH is seen, the data is passed to the user in buffer size units.

192.168.43.10	37.252.227.51	TCP	75 49116 → 5938 [PSH, ACK] Seq=1 Ack=1 Win=2931
37.252.227.51	192.168.43.10	TCP	75 5938 → 49116 [PSH, ACK] Seq=1 Ack=10 Win=131
192.168.43.10	37.252.227.51	TCP	66 49116 → 5938 [ACK] Seq=10 Ack=10 Win=29312 L

The TCP handshake/stream is finished using the [FIN ACK] tcp packet. (probably it helps to free some connection points).

192.168.43.10	37.252.227.51	TCP	66 49116 → 5938 [FIN, ACK] Seq=19
---------------	---------------	-----	-----------------------------------

Also when another device is used to connect the TV instance using the ID, similar queries and handshakes take place in order to establish connection between the two peers. Once a connection is established, it is followed by large sequence (too many) of [PSH ACK] and [ACK] packets exchange in which indicates both end sending data to each other plus demanding for the data immediately. As shown

192.168.43.10	217.146.11.3	TCP	90 43954 → 5938 [PSH, ACK] Seq=133062
217.146.11.3	192.168.43.10	TCP	90 5938 → 43954 [PSH, ACK] Seq=134834
192.168.43.10	217.146.11.3	TCP	66 43954 → 5938 [ACK] Seq=133086 Ack=1
192.168.43.10	213.131.255.30	TCP	90 47528 → 5938 [PSH, ACK] Seq=7299 Ac
213.131.255.30	192.168.43.10	TCP	90 5938 → 47528 [PSH, ACK] Seq=22690 A
192.168.43.10	213.131.255.30	TCP	66 47528 → 5938 [ACK] Seq=7323 Ack=227
192.168.43.10	217.146.11.3	TCP	90 43954 → 5938 [PSH, ACK] Seq=133086
192.168.43.10	217.146.11.3	TCP	90 43954 → 5938 [PSH, ACK] Seq=133110

Sol4.

Importance of Protocols used by team viewer (wrt app itself):

TCP: Team Viewer involves fetching and transferring data from both ends live i.e continuous and quickly. Its bandwidth probing and congestion control will attempt to use all of the available bandwidth between peers transferring content as quick as possible while being friendly to other (TCP) traffic on the same link. This is the foremost requirement of an Remote Desktop sharing app. Also it allows prefetching of data helping in maintaining the smooth (nearly smooth) view of the shared desktop and continuous input being given.

Also TCP is reliable, hence the frames transmitted are not lost preventing the ambiguous behaviour in commands given by remote client or data sent by shared desktop.

UDP: It is not used as such for data transfer since it is not reliable as it doesn't maintain the state of connection and doesn't guarantee or make attempts that packet will reach the destination. It is only used for DNS queries.

DNS: Used at various stage to resolve the domain name. Apart from this it also has a major advantage.

Suppose the IP address of a server gets changed or server supports multiple IP mappings. Then all these IPs needn't be hardcoded in the client app only the domain name can be used which can be mapped to any one of the IPs available.

IPv4 : Used for logically determining the location of source and destination in the network. It also provides error detection and correction techniques.

Ethernet II : Used to encode the information about source and destination physical(i.e MAC) address. Also it contains information about error detection and correction.

(Also **NTP** was invoked at sometimes but the source invoking it is not clear. Maybe invoked by OS or TV app for time synchronization.)

Sol5. (graphs for raw_data5.pcapng has been shown here. Also the images are corresponding to this data. Rest values are given in tabular format)

Graph shows the **throughput and RTT starting from connection establishment**, then sequence of transaction between two peer devices.

Total packets and bytes captured and Average packet size.(shown below). Packets: 52352 , Avg. Packet Size: 153.5 Bytes.

Measurement	Captured	Displayed
Packets	52352	52352 (100.0%)

No. of Packets lost	600	1	0
No. of TCP packets from A to B	30,497	1575	402
No. of TCP packets from B to A	20,973	1264	317
No. of UDP packets	331(none between A and B)	73 (none between A and B)	24 (none between A and B)
No. of Responses/request	0.67(because more data is sent then recieved)	1.25	1.27

Sol6. Multiple IPs were detected to be used as shown in the following images.(Infact almost every new connection tried resulted in the new IP address).But the IP address didnt changed once a connection is established. Changing IP could be because of the various possible servers used by the Team Viewer App, which might be changing with the time of day or every new route being established to Server. In P2P connection the shorter route that can be established between 2 peers more faster will the data transfer.Also large number of routes/server are needed for faster, countinous and large data transfer reasoning the change at every new connection.Remote Desktop Control app requires transfer of live data and commands which requires large and contiguous transfer of data, also there can be many connection (Some IPs are: 213.131.255.40, 217.146.11.3, 217.146.11.2 etc.)

Images showing various IP used (in differnet connection attempts).
